1 Introduction

The Objective of this project is to build a Turkish Lira banknotes image recognizer through a Convolutional Neural Network. The proposed solution, based on Tensorflow libraries, contains steps to dinamically download the dataset, preprocess the images in it and use the processed images to train a Convolutional Neural Network in recognizing and classifying them. Since the given dataset contains many images and since the request is to classify some precise details of them, it's expected to achieve good results from the proposed solution and in particular from the proposed model.

2 The Turkish Lira banknotes dataset

The chosen dataset <add ref> is originally composed of 6000 images of Turkish Lira banknotes, organized in folders grouping banknotes by their value and already splitted in training and validation set.

2.1 Preprocessing techniques applied to the dataset

To start the pre-processing phase, it's needed to scale the images to a more appropriate size to not overload the machine memory; the size scale factor used in this project is 5. The given dataset was provided with two text files listing the images belonging to the training and to the validation datasets; using this lists, the images files have been divided in the two respective labeled datasets. The training dataset has been created using a "prefetch dataset" and the validation dataset has been created using a "repeat dataset" both using also batching and caching techniques.

2.2 Considered algorithms and their implmentation

?

3 Scalability of the proposed solution

The Scalability of this project is granted by (batching, caching, img scaling, ? ...)

4 Experiments and results

Different models have been tested during the developing process; in this section some of those will be shown and the relative results will be discussed.

4.1 Model summary

For each tested model the following data will be reported:

- The NN architecture
- Hyperparameters used
- Data on accuracy for three repeated runs
- Graph of one of the runs
- Comment on the architecture and results

Each model will be trained for exactly 20 epochs in order to get consistent results

In the layer tables the input layer will not be reported, as it always corresponds to resized image size (144,256,3).

Also note that some abbreviations are used in the Layer Config field in order to for the table to fit:

- k stands for kernel size
- s stands for strides
- f stands for filters

4.2 Models

4.2.1 Baseline Model

Layer Type	Layer Config	Activation	Output	Params
Convolution(Conv2d)	k=5, s=3, f=5	relu	48,86,5	380
Flatten(Flatten)	/	relu	20640	0
Dense(Dense)	u = 64	relu	64	1321024
$\mathrm{Dense}(\mathtt{Dense})$	u = 6	$\operatorname{softmax}$	64	390

Param	Value
Batch Size	32
Optimizer	Adam
Base lr	0.001

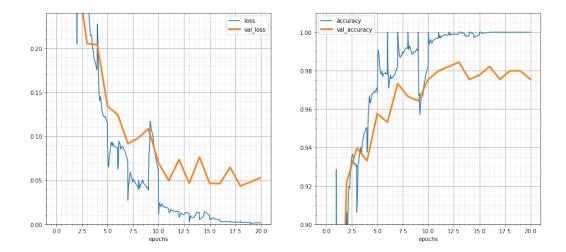

Figure 1: Graph of the first run

Run	Loss	V.Loss	Acc.	V.Acc.	Δ Acc.
1	0.0016	0.0530	1.0000	0.9754	0.0246
2	0.0012	0.0342	1.0000	0.9821	0.0179

Avg	1.2589e-04	0.0653	1.0000	0.9889	0.0112

5 Conclusions

As seen in the previous sections, after a few experiments, this project has been successful in classifying the images of Turkish Lira banknotes with high accuracy and low data loss. (altro?)
